

# What I have added

Script:

```
<script>
  const panels = document.querySelectorAll('.panel');

  function toggleOpen() {
    console.log("Hello");
    this.classList.toggle('open');
  }

  function toggleActive(e) {
    console.log(e.propertyName);
    if (e.propertyName.includes('flex')) {
      this.classList.toggle('open-active');
    }
  }

  // Function to automatically toggle the panels step by step
  function autoTogglePanels() {
    panels.forEach((panel, index) => {
      setTimeout(() => {
        panel.click(); // Simulate a click on each panel
      }, index * 1000); // Adjust the delay as needed
    });

    // Untoggle the panels after a certain time (adjust as needed)
    setTimeout(() => {
      panels.forEach(panel => panel.click());
    }, panels.length * 1000);
  }

  // Automatically toggle the panels when the page is loaded
  window.addEventListener('load', autoTogglePanels);
</script>
```

As an extra feature, I have added script to automatically toggle the panels when the page is visited. This functionality simulates a click event on each panel with a specified delay between each, creating a step-by-step toggling effect. After all panels have been toggled, the script waits for a set duration before untoggling the panels in reverse order.

```
// Function to automatically toggle the panels step by step
function autoTogglePanels() {
  panels.forEach((panel, index) => {
    setTimeout(() => {
      panel.click(); // Simulate a click on each panel
    }, index * 1000); // Adjust the delay as needed
  });

  // Untoggle the panels after a certain time (adjust as needed)
  setTimeout(() => {
    panels.forEach(panel => panel.click());
  }, panels.length * 1000);
}

// Automatically toggle the panels when the page is loaded
window.addEventListener('load', autoTogglePanels);
```

The added JavaScript code introduces a function named `autoTogglePanels` which makes the panels on the webpage automatically open and close in a timed sequence when the page loads. It uses the function called `autoTogglePanels` that iterates through each panel, simulating a click on each with a delay between clicks. This creates a step-by-step toggling effect. After all panels are toggled, there's another delay before the script untoggles the panels in reverse order. This addition adds a cool interactive feature to the webpage, making it more dynamic.
